

Haart-less and Healthy

Checking HIV for 20 years—with prednisone alone

August 1, 2005 By Laura Whitehorn

New York

HIV Treatment Educator

Diagnosed 1982

New Yorker Mark Milano has had CD4s as low as 74, but he's found a way to stay med-free and healthy. His secret? A steroid that, oddly, suppresses your immune system. Say what? Read on.

The Discovery: “In 1985, I had sarcoidosis, a non-HIV autoimmune condition. [Corticosteroid] prednisone cleared it up. I kept taking it for the condition—and my CD4s held up. Then, I read that prednisone slows HIV. When I tried testosterone instead, I lost CD4s.”

The Take: “Dosing is key. Taking too much or taking it daily causes hormone problems. I take 15 mg every other day, with only minor muscle loss and fat gain (which may just be age!). I'll give up muscle for the CD4s!”

The Science: “HIV needs activated CD4 cells to reproduce, and low-dose prednisone suppresses immune activity just enough to slow down HIV.”

The Result: “I'm healthy and active. My CD4s stay around 400, though my viral load is 475,000.

The Future: “If my CD4s settle at 200, I'll be happy to go on HIV meds.”

The Feelings: “I'm glad I stuck with what I felt was right. I don't know if it will work for others, but it works for me.”
